

Vidyut: Exploiting Power Line Infrastructure for Enterprise Wireless Networks

Vivek Yenamandra and Kannan Srinivasan

THE OHIO STATE UNIVERSITY

Motivation

- Increasing demand for wireless capacity
 - Proliferation of BYOD in workplaces
 - Data Intensive applications: Video Streaming, Teleconferencing, Surveillance etc.
- Scarce spectrum resources

Growing emphasis for spectrally efficient large capacity wireless networks

Enterprise WLAN

Enterprise WLAN

Ethernet Backbone

Enterprise WLAN

Ethernet Backbone

AP

The APs share medium(time/frequency/code) to mitigate interference

Dense Client Distribution

Alternative?

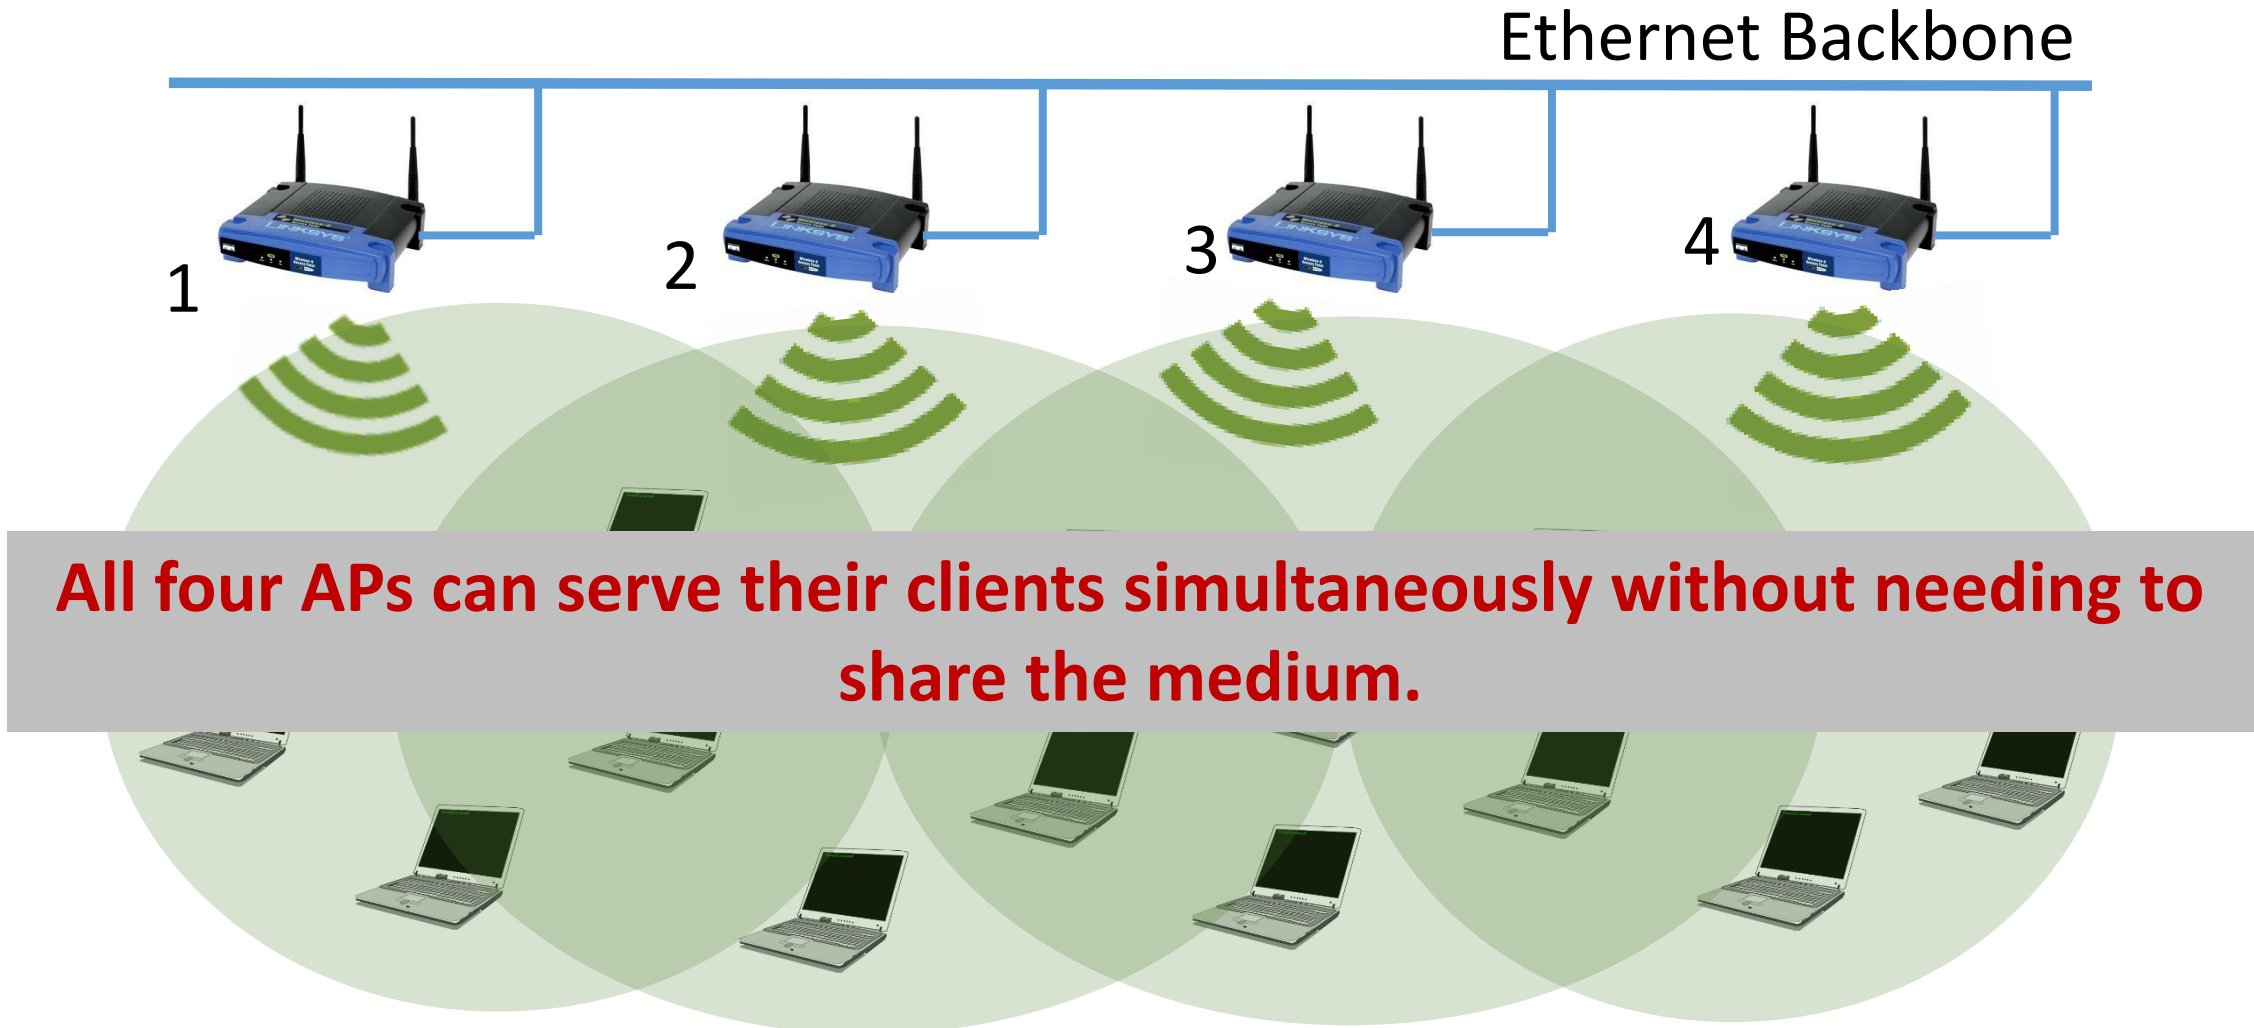

Ethernet Backbone

**Multiple APs coordinate to emulate a single virtual AP
with many antennas – Network MIMO**

Why Network MIMO?

Network MIMO Prerequisite

**The coordinating APs *need* to be synchronized
in frequency and time**

Network MIMO Implementation¹

[1]. Hariharan et.al, JMB: Scaling Wireless Capacity with User Demands, SIGCOMM, 2012

Network MIMO Implementation

Ethernet Backbone

Network MIMO Implementation

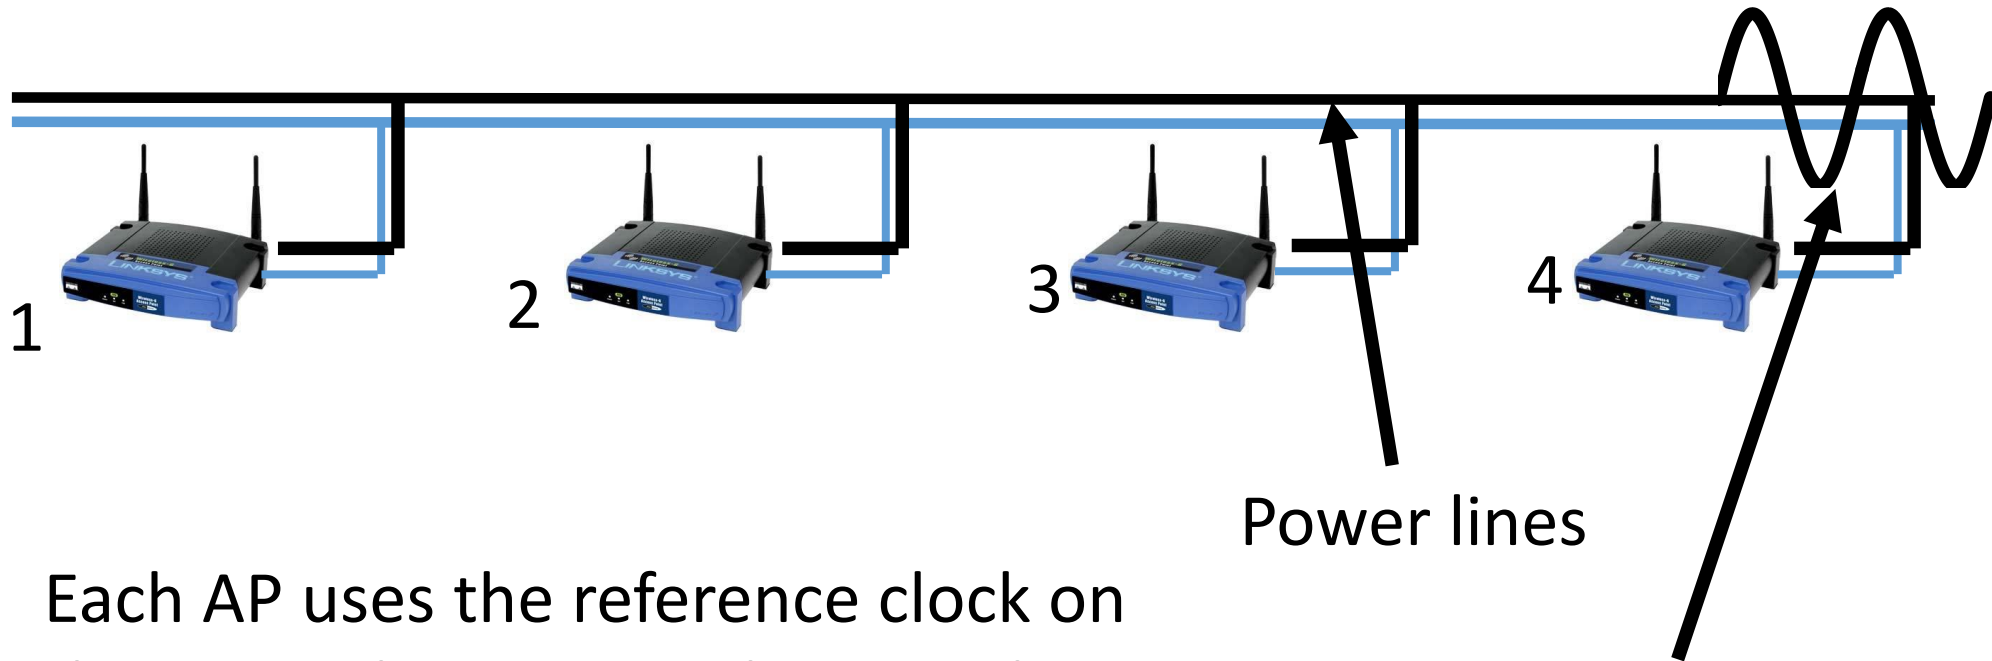

The transmission range of the lead AP *limits* the number of APs that can coordinate to emulate a single large virtual AP

How can we synchronize *across* clusters?

Vidyut

Each AP uses the reference clock on the power lines to synchronize their own carrier clocks using a PLL.

Reference Clock transmitted on the Power Lines

Vidyut

Each AP uses the reference clock on

All APs are synchronized

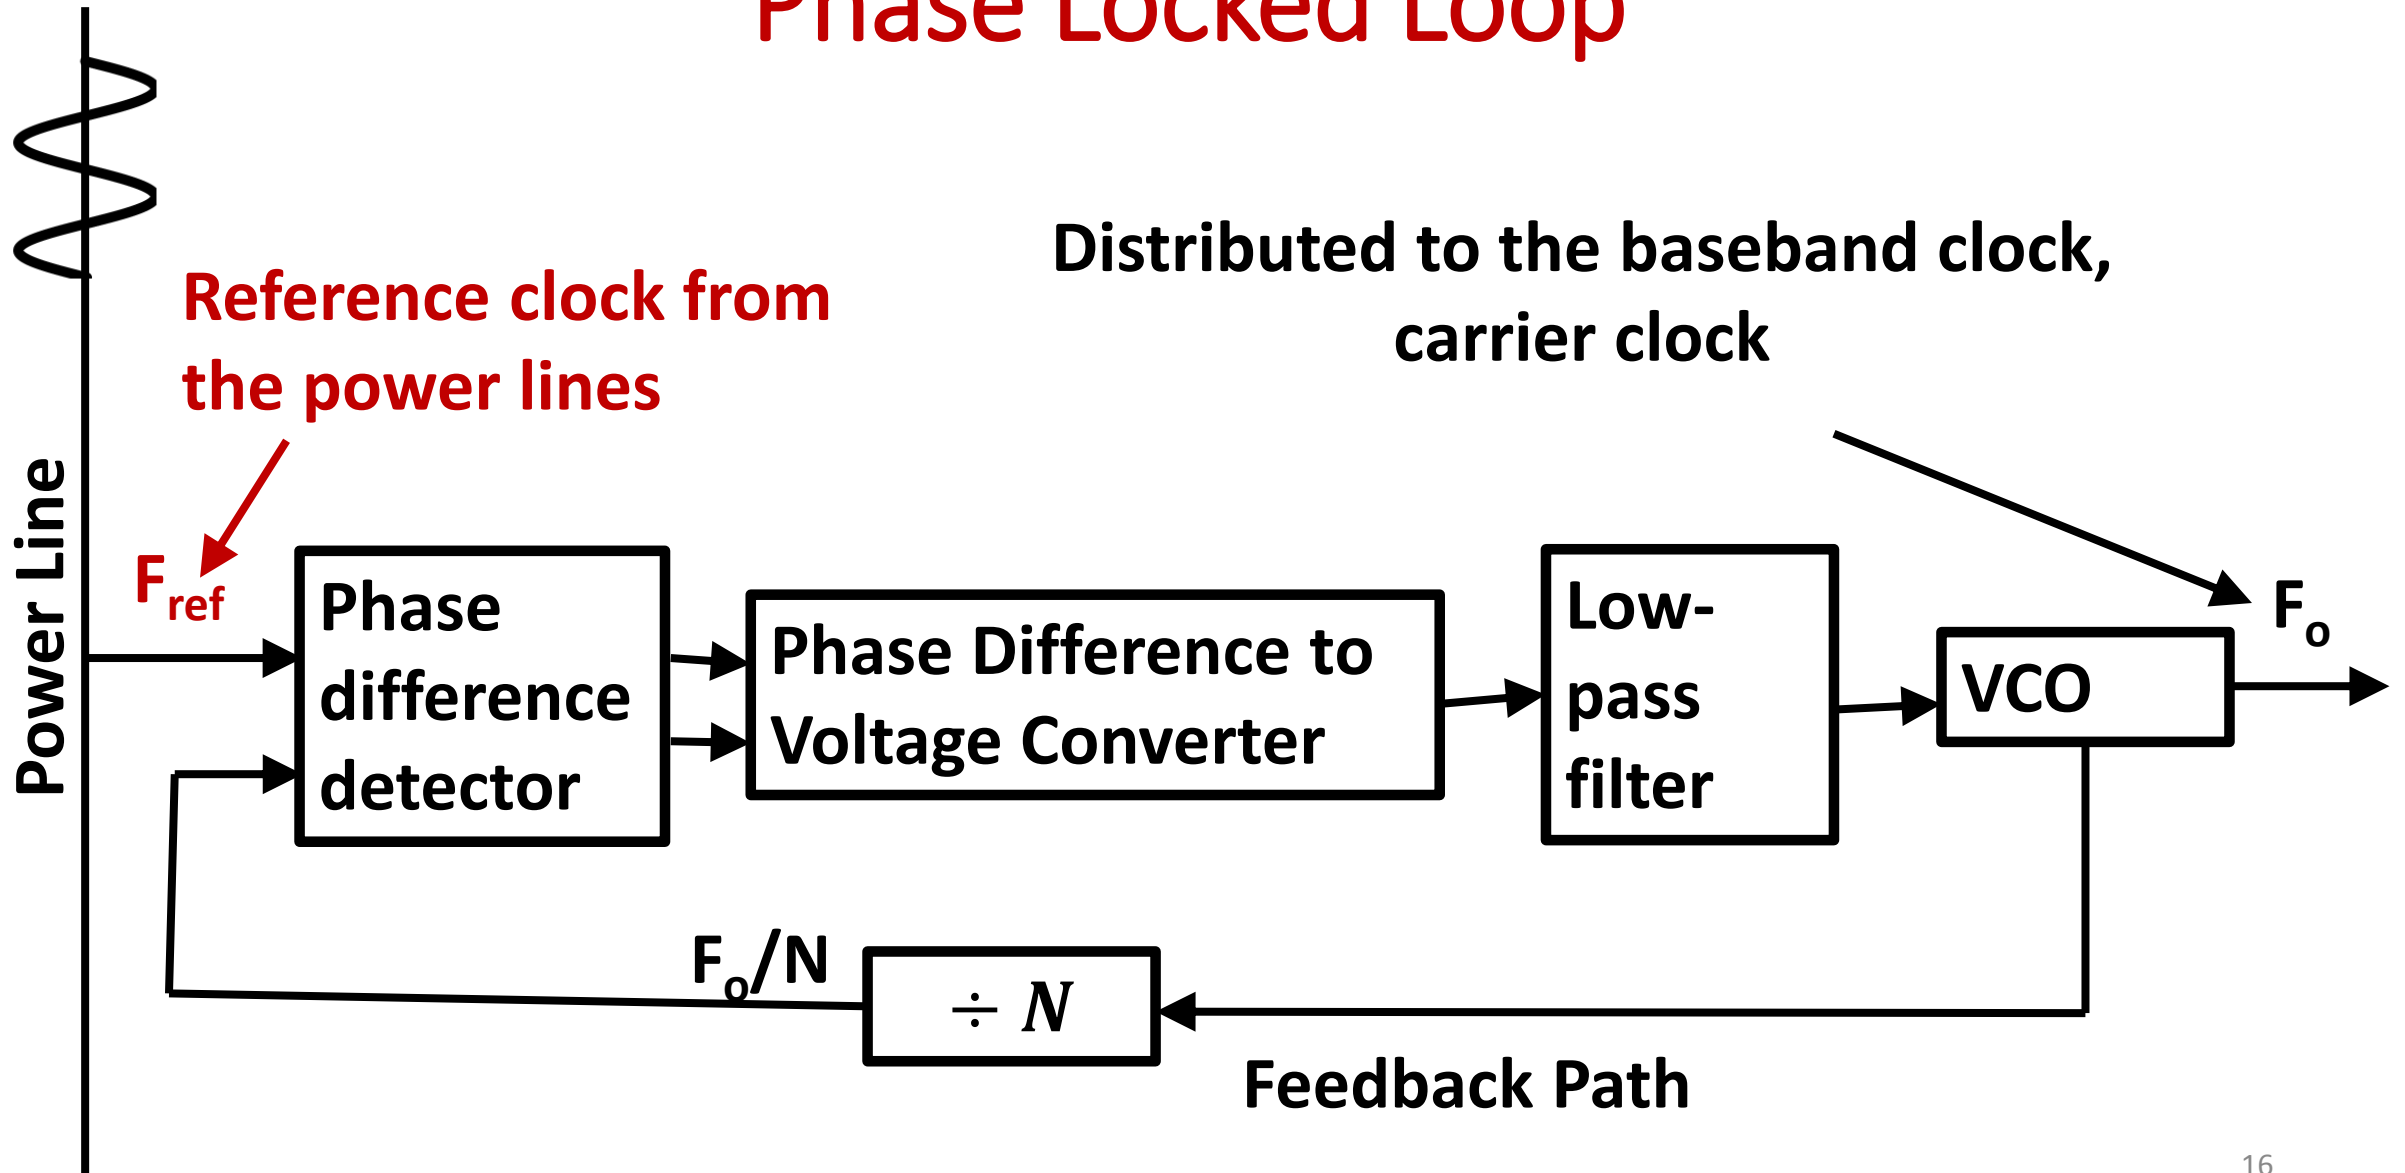

own carrier clocks using a PLL.

transmitted on
the Power Lines

Phase Locked Loop

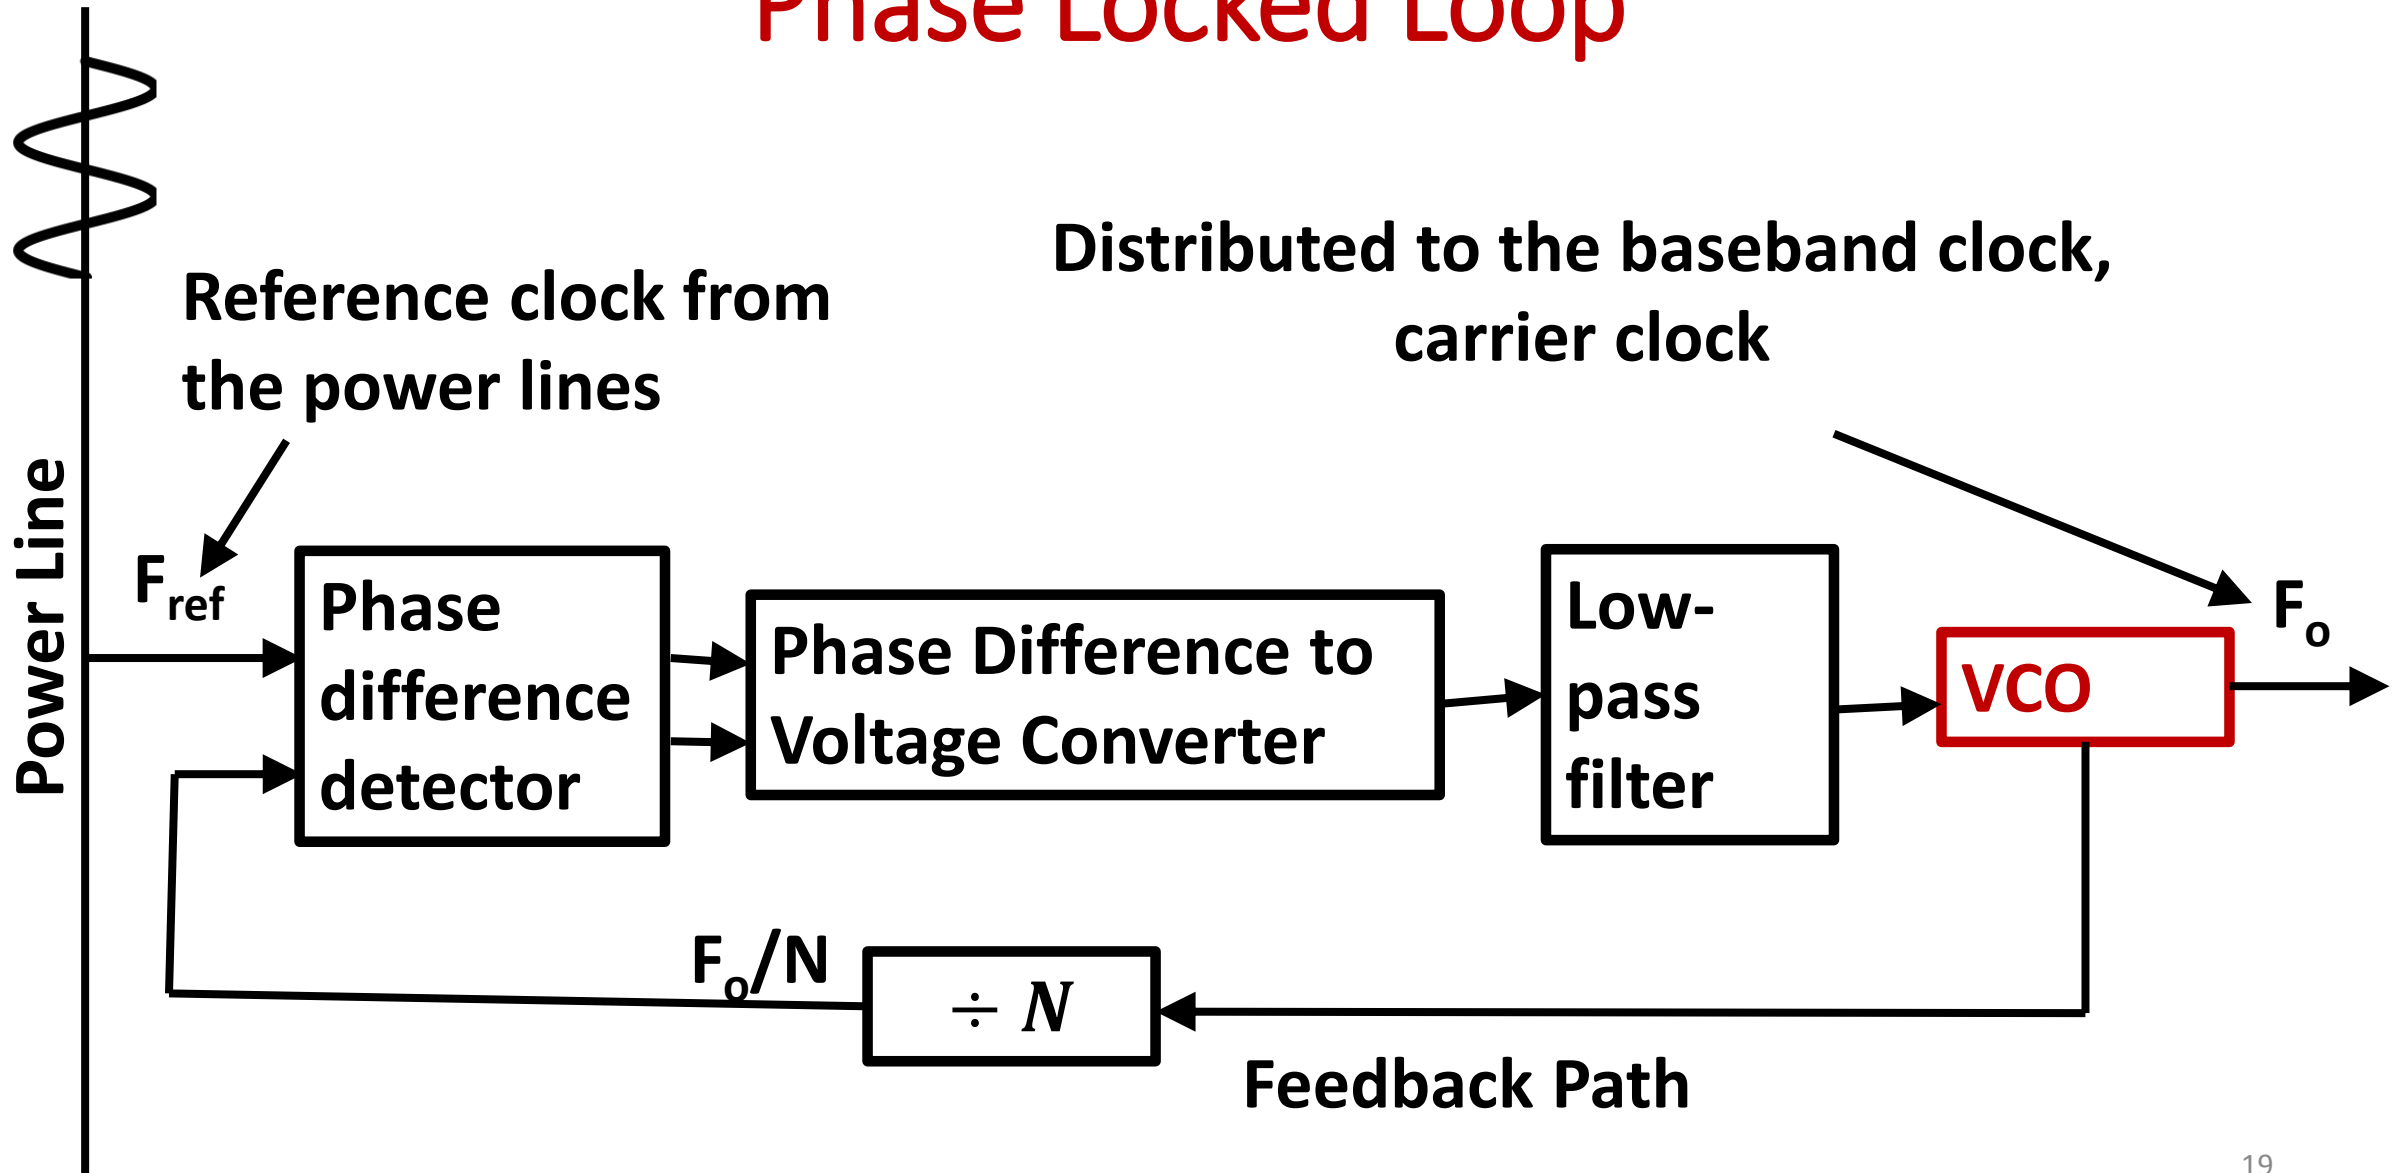

Phase Locked Loop

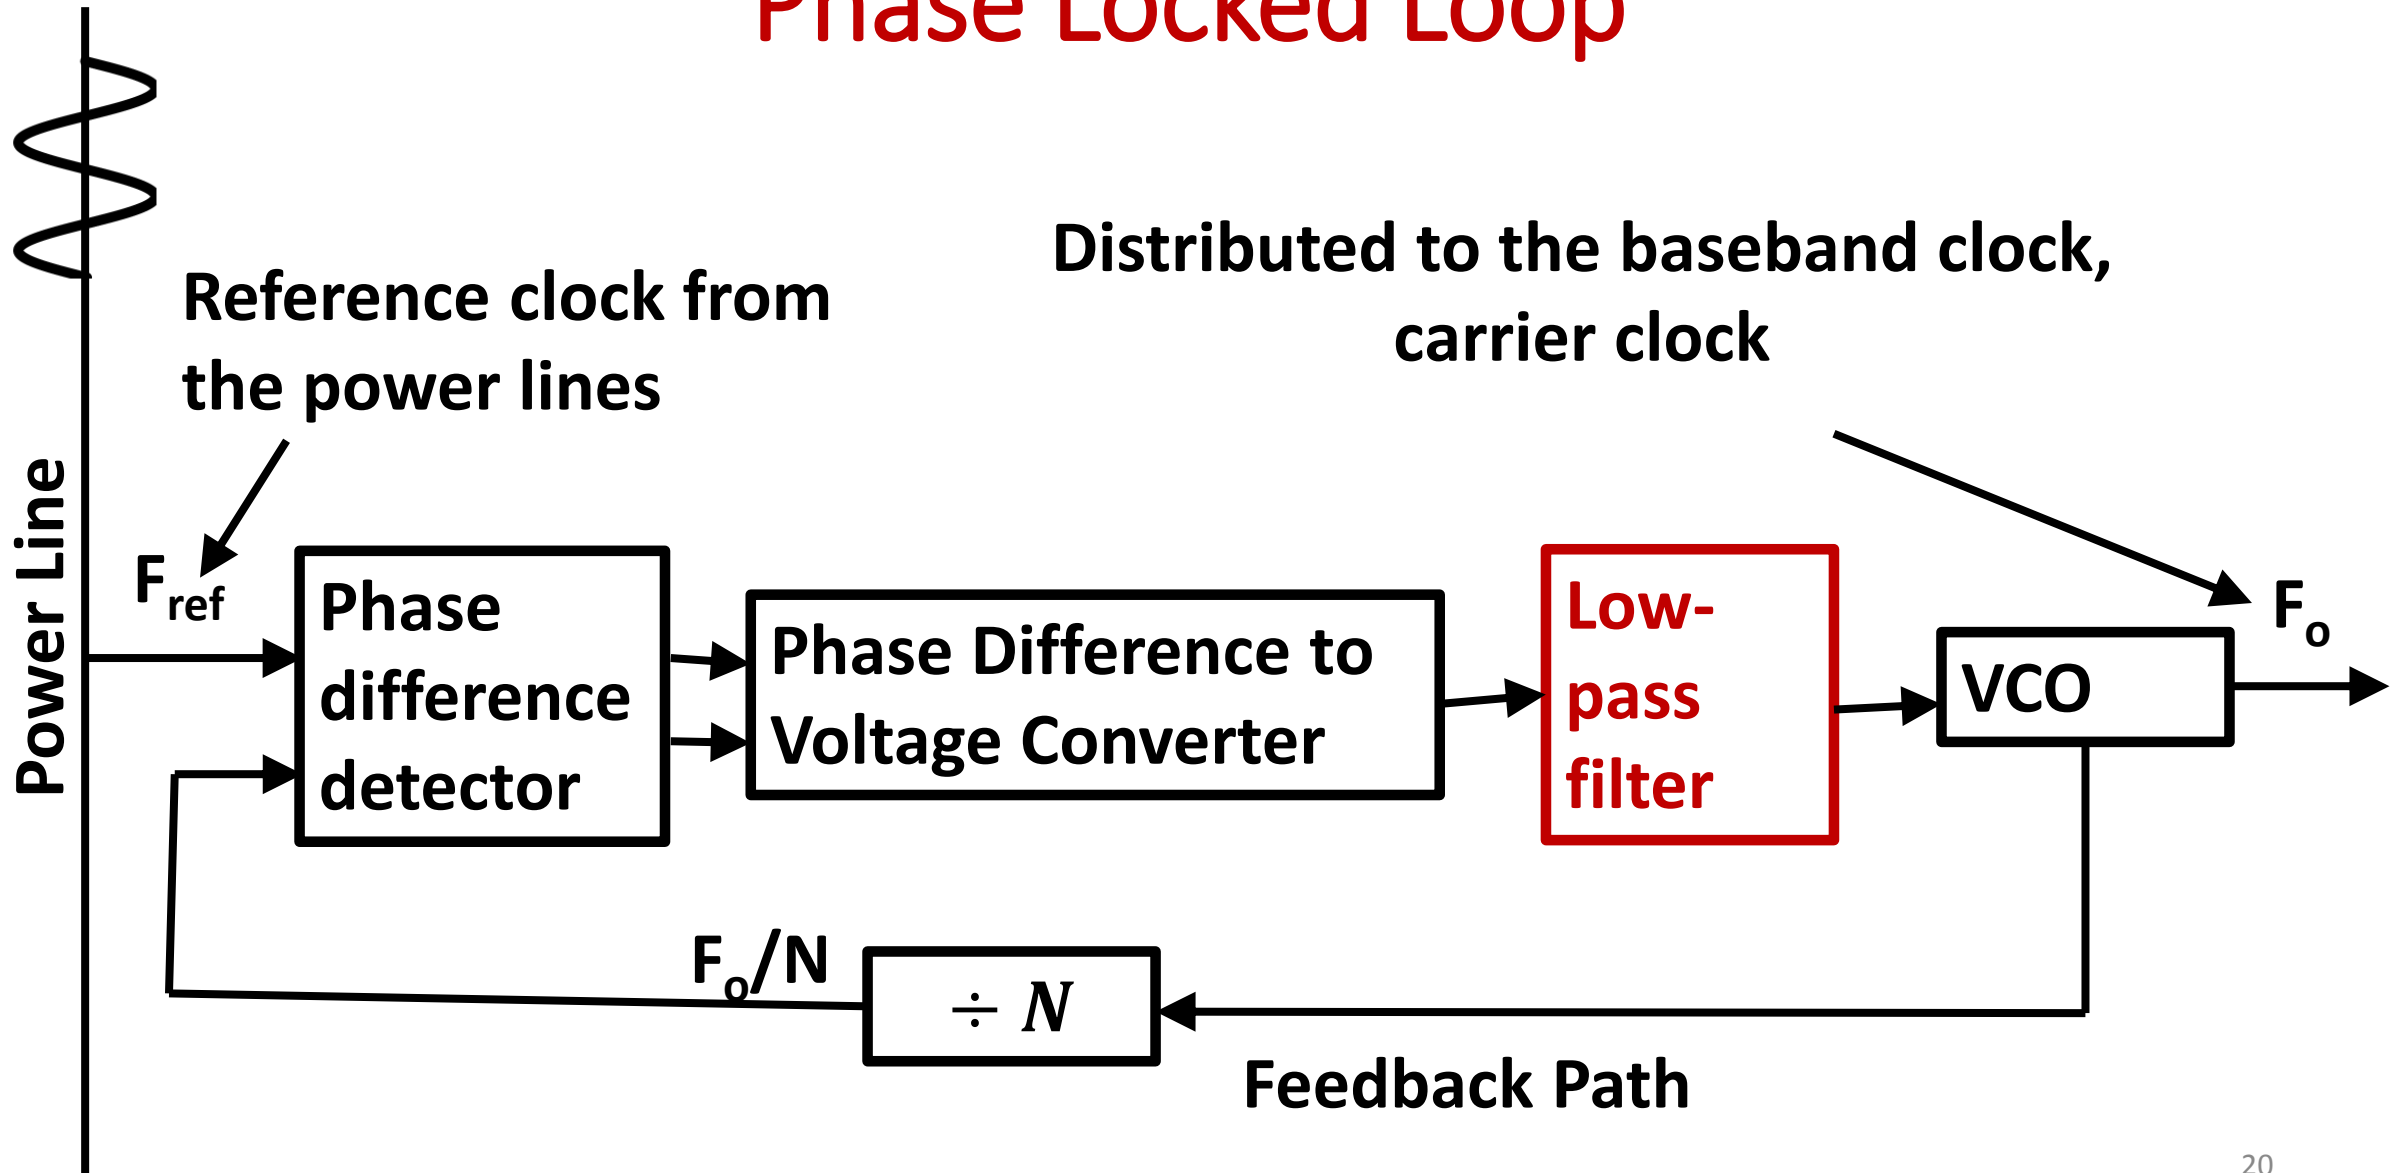

Phase Locked Loop

Phase Locked Loop

Phase Locked Loop

How to select the reference frequency?

Selecting the Reference Frequency

- Determined by the Power Distribution Network
 - Elements like transformers/distribution panels

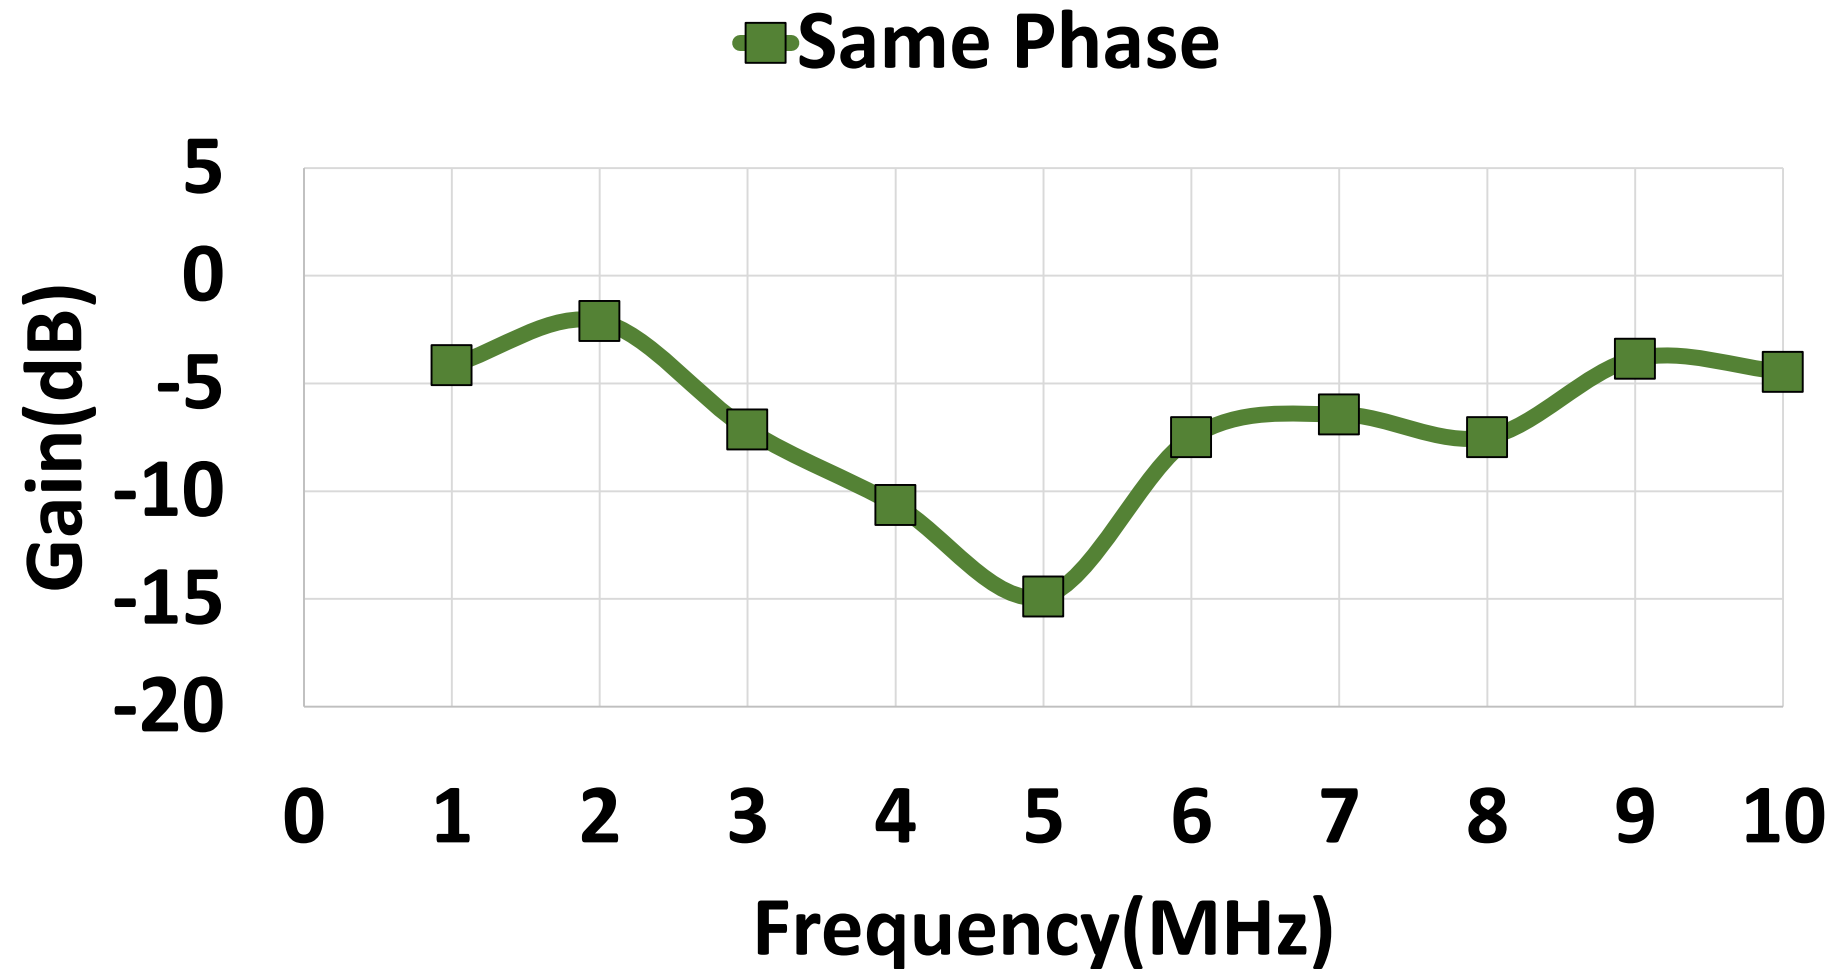

Measuring Characteristics

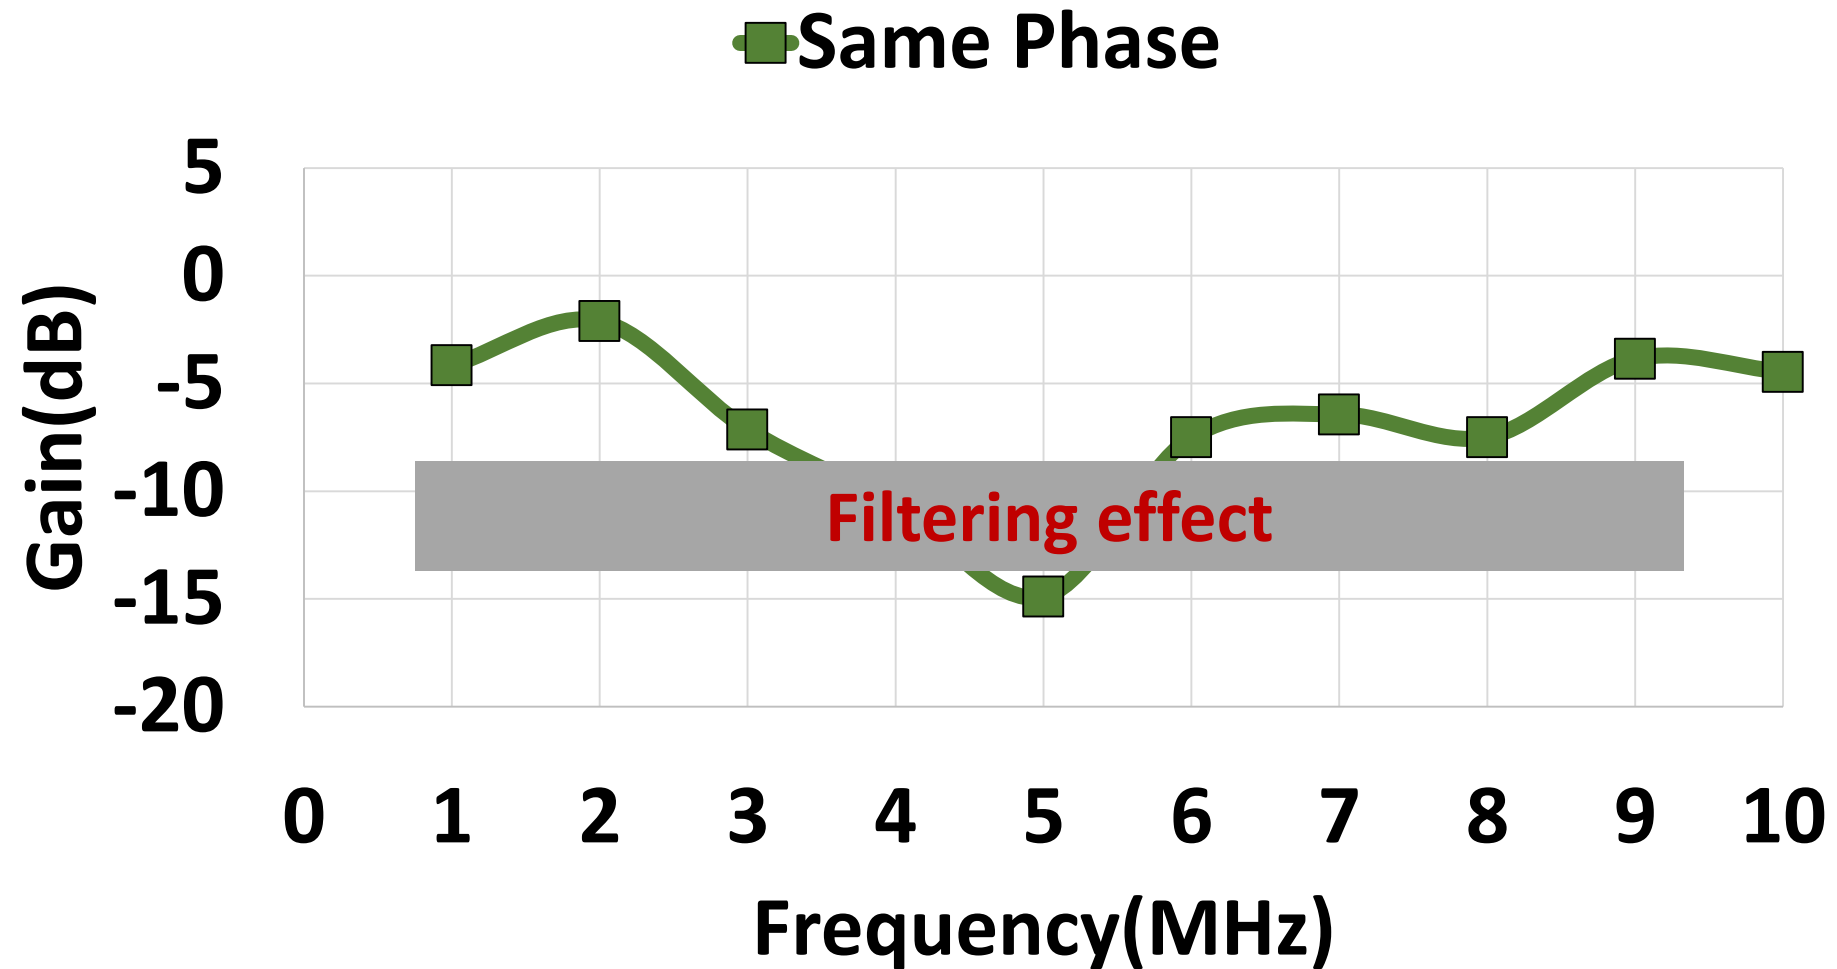

Transformer Response

Transformer Response

Transformer Response

Three-Phase Power Supply

The three phases are *physically* isolated

Do we need a separate reference clock for each phase?

Transformer Response

Transformer Response

Transformer Response

Transformer Response

Evaluation: How effective is Vidyut's phase synchronization?

Evaluating Phase Mismatch

Both APs synchronized using Vidyut

$$\Phi_{\text{mismatch}} = (F_{\text{received}} - F_{\text{pilot}}) \times T + \Phi_{\text{initial}}$$

Evaluating Phase Mismatch

Both APs synchronized using Vidyut

When both nodes are synchronized, $F_{\text{received}} = F_{\text{pilot}}$ making Φ_{mismatch} constant over time

$$\Phi_{\text{mismatch}} = (F_{\text{received}} - F_{\text{pilot}}) \times t + \Phi_{\text{initial}}$$

Phase Synchronization Over Time

Phase Synchronization Over Time

Phase Synchronization Over Time

Power Distribution Network

- Power lines are designed to carry power at 50/60 Hz
 - The higher frequency of the reference clock attenuates over distance.

Each *AP regenerates* the reference clock back on to the power lines

Clock Regeneration

Each AP feeds back a Reference clock phase matched to *Ref In* back on to the power lines.

Clock Regeneration

Enables synchronization of spatially distant APs

Each AP feeds back a Reference clock phase matched to *Ref In* back on to the power lines.

Clock Regeneration

Each AP feeds back a Reference clock phase matched to *Ref In* back on to the power lines.

Regeneration Effect on Clock Synchronization

- Each clock regeneration adds a distinctive phase noise characteristics
- The phase mismatch between a pair of nodes does not correlate with the number of clock regenerating sources between them.
- Details in the paper.

Achieving Distributed Time Synchronization

- We adopt the principles proposed in [1].
- Utilize the stable power frequency to achieve distributed time synchronization
- Details in the paper.

[1]. Rowe et.al, Low-power clock synchronization using electromagnetic energy radiating from ac power lines, SENSYS, 2009

Implementation

- Eight NI based SDR nodes
 - NI-5791 RF Front End
 - Accepts Reference Input/ Drives PLL output
 - 10 MHz OFDM in the 2.4 GHz ISM Band
 - PXIe-7965R FPGA ..
- Agilent 8648C : 10 MHz Reference Clock

32m

We interface the nodes to random power outlets across all three phases of power supply

Evaluation: Performance gains of Vidyut-enabled
Network MIMO.

Setup

Divide the eight nodes into four APs and four clients.

Place the nodes at random locations as before such that the APs are divided into *two* clusters

Each cluster has clients to service

Compared schemes: MegaMIMO, NEMOx¹

[1]. Zhang et.al, Scalable Network MIMO for wireless networks, Mobicom, 2013

NEMOx

Ethernet Backbone

NEMOx

Ethernet Backbone

Throughput Gain

As the Number of Clusters Increases

MATLAB based simulation

Account for increase in noise at each client due to phase mismatch between APs as their number increases.

Provisions slackness for variance in time synchronization

MegaMIMO and NEMOx are implemented using a TDMA over CSMA type MAC

As the Number of Clusters Increase

Future Work

- Client selection in the clusters is an important design decision that has been left for future work.
- As the number of nodes participating in Network MIMO increases, the challenge of processing the resulting large volumes of data needs to be addressed.
- Distributed synchronization across multiple collision domains can enable scalable implementation of exciting theoretical and systems work.

Thanks!

Vidyut

Language of Origin: Sanskrit

Definition: Electricity

Alternate Pronunciations: Probably will not help.
